The Effect of the Training of Gradual Muscular Relaxation in Reducing Psychological Stress among Students of the Faculty of Sports Science and Physical Activity

Haggag M*

Associate Professor of Sport Psychology, King Saud University, Saudi Arabia.

Abstract

Background: Psychological stress is a major risk factor for the development and progression of a number of diseases, including cardiovascular disease, cancer, arthritis, and major depression [1]. A fact known by the scientific community is that emotions in general, and stress in particular, produce interrelated functional changes, mainly through the vegetative nervous system, the endocrine system, and the immune system [1, 2].

Subjects with a protracted state of tension greatly suffer from psychological, physiological and behavioral effects which over-time lead to harmful consequences [2].

The contemporary society maintains individuals in a constant struggle for success without taking into account their needs and how much all this costs them. For professional sportsmen, mood and level of stress have been always considered aspect they must learn to control. Moreover, an increase of alteration of mood states and of levels of stress has reported in young students [3-5]. Also, it was reported that Youth is the period of contradictions in which the individuals experience many emotional, behavioral, sexual, economic, academic and social conflicts which result in social and physical changes [6, 7].

Thus, in this period the emotional health of university youth be-

Introduction

Psychological stress is a major risk factor for the development and progression of a number of diseases, including cardiovascular disease, cancer, arthritis, and major depression [1]. A fact known by the scientific community is that emotions in general, and stress in particular, produce interrelated functional changes, mainly through the vegetative nervous system, the endocrine system, and the immune system [1, 2].

Subjects with a protracted state of tension greatly suffer from psychological, physiological and behavioral effects which over-time lead to harmful consequences [2].

comes one of the important components of social health [6-8]. For this reason, it is important to detect the status of psychological stress among younger ages and to find good solutions to overcome these contradictions.

Progressive muscle relaxation (PMR) is a technique for reducing stress and anxiety by alternately tensing and relaxing the muscles as previously reported [9-11]. It mainly requires both a physical and a mental component. Previous research recommended several benefits of PMR technique including a reduction in salivary cortisol levels and generalized anxiety [10] decreased blood pressure and heart rate [10, 12], decreased headaches [13], better management of cardiac rehabilitation [14] improvement of quality of life of patients with chronic diseases or following severe surgical operations [15, 16]. Thus it is better to use PMR technique in for ameliorating psychological stress among younger ages.

Thus, it is important to identify the psychological stress among younger ages and find out an alternative non-drug remedy to overcome this stress. In this regard, the aim of the present study was to characterize the rate of psychological stress among students of faculty of sports sciences and to evaluate the efficacy of a particular relaxing gradual technique called progressive muscle relaxing (PMR) for ameliorating the mood and for returning the psychological stress parameters into normal levels.

Materials and Methods

Participants

A total of 40 of Students of Faculty of Sport Sciences aged 18-21 years old from College of Sport Sciences & Physical Activity, King Saud University, Riyadh, Saudi Arabia, were enrolled in this study. Students who had serious acute or chronic health problems such as diabetes, endocrine disorders, cardiovascular disease, systemic infections, musculoskeletal disorders, or concentration problems or psychological disorders such as depression, or post-traumatic stress disorders that might change the psychological stress parameters were excluded from this study. Based upon psychological stress score (PSS), the students classified into two groups; control (n=20) and Psy. stress group (n=20). At a statistical power of 96% and a significance level of ≤ 0.05, the sample size of the study was estimated to be 42 participants to compensate for an estimated 12% dropout rate. The study was approved by the Research Ethics Committee of King Saud University, and all participants gave signed informed consent. Baseline demographic and characteristics of all participants were shown in Table 1.

Assessments of Psychological Stress

Pre-validated psychological stress scales were applied to evaluate the degree of social and psychological stress measures among students. These measures were evaluated according to previously performed stress scales and that test-retest reliability coefficient of 0.80 or higher for these statistics are indicative of acceptable test-retest reliability [17, 18].

Assessments of Progressive Muscle Relaxation (PMR)

Progressive muscle relaxation (PMR) is a technique for reducing stress and anxiety by alternately tensing and relaxing the muscles as previously reported [9, 10]. In this techniques all students performed the PMR training interventions 2 times/week for 12 weeks.

In this training program, the physical component involves tensing and relaxing of muscle groups over the legs, abdomen, chest, arms, and face. In a sequential pattern, with eyes closed, the tension of the individual place in a given muscle group purposefully for approximately 10 seconds and then releases it for 20 seconds before continuing with the next muscle group [9-11].

The mental component requires that the individual focuses on the distinction between the feelings of tension and relaxation. Relaxation must be attempted in order to reduce pain or pain perception and tension, create a pleasant mental state, enhance the performance of physical activities and help in the relationship with others [11, 12].

Statistical Analysis

An SPSS software (Statistical Package for the Social Sciences, version 18.0, SPSS Inc. Chicago, IL, USA) was used to perform statistical analyses. The qualitative variables were presented in terms of frequencies and percentage, and the quantitative variables were presented using mean and standard deviation. For analyses within the groups, we used a t-test for paired data. The unpaired t-test was used for within and between groups. The comparison and correlation of the studied parameters were investigated using both Student’s t-test and Pearson's correlation coefficient, respectively.

Results

In this study, all psychological stress parameters; family stress, study stress, economic stress, and social stress, and the effect of progressive muscle training interventions on the degree of psychological stress were characterized in 40 healthy university students. Based on the degree of the severity of psychological stress scores, the participants classified into two groups; control healthy (n=20) and psychological stress (n=20) as shown in table (1). There is no significant difference in age, BMI, but WHR of adiposity showed little non-significant change in psychological students compared with healthy controls (table 1). The results showed that students with higher scores of psychological stress parameters require more non-drug support interventions.

In this current study, both control and psychological students participated in PMR training interventions for 12 weeks (2 times/week) and the effect of PMR - exercise on psychological stress was evaluated as shown in Table (2) and Figure (1). PMR-Post results showed that all psychological parameters were significantly declined and improved in all healthy (P=0.01) and students with psychological stress (P=0.001) as shown in Table (2). The data showed that PMR training interventions program improve psychological stress gradually during the period of treatment as shown in Figure (1).

Discussion

In this study, psychological stress parameters were significantly re-
supported in 50% (20/40) of the participated students. These results greatly require to find out more non-drug supportive interventions for the reduction of psychological stress among younger ages. The data matched with those who reported significant collateral damage associated with severe diseases among both older and younger ages [1, 2]. A harmful consequence was reported among youth and young students [3-5], in which disturbances were reported in all psychological, physiological and behavioral processes [2]. In addition, psychological stress was reported as a major risk factor for the development and progression of a number of diseases, including cardiovascular disease, cancer, arthritis, and major depression [1]. These consequences in turn greatly affect in many emotional, behavioral, sexual, economic, academic and social conflicts of young ages and result in social and physical changes [6, 7].

Recently, the importance of psychological skills training (PST) techniques and other related training techniques have been recognized and the number of studies on athletes or other patient subjects using psychological training strategies to improve psychological status [19-21]. One of the most training techniques affecting on psychological stress is Progressive muscle relaxation (PMR) [9-11]. It showed to reduce stress and anxiety by alternating tensing and relaxing the muscles as previously reported [9-11].

11. It mainly requires both a physical and a mental component of the subject during treatment sessions.

In this current study, both control and psychological students participated in PMR training interventions for 12 weeks (2 times/week). PMR-Post results showed that all psychological parameters were significantly declined and improved in all healthy (P=0.01) and students with psychological stress (P=0.001). The data showed that PMR training interventions program improve psychological stress gradually during the period of treatment which support its efficacy as non-drug strategy for treating psychological stress and its consequences among younger ages.

Previous research reports recommended several benefits of PMR technique including a reduction in salivary cortisol levels and generalized anxiety [10], decreased blood pressure and heart rate [10, 12], decreased headaches [13], better management of cardiac rehabilitation [14] improvement of quality of life of patients with chronic diseases or following severe surgical operations [15-16]. Thus it is better to use PMR technique in for ameliorating psychological stress among younger ages. Previous treatment strategies with predominant skeletal muscle components also tend to produce greater muscular effects particularly; a decrease in muscle tone and tension. Different versions including, PMR, biofeedback, yoga, and systematic breathing are the most investigated techniques in this domain [22].

Progressive muscle relaxation and its derivations have received the most attention in scientific context whereas it significantly deliberate and continuously reduce of tension in specific muscle groups of the locomotor system [9]. A review on the use of PMR in clinical trials revealed moderate to large effect sizes on the effectiveness of PMR [23, 24].

Conclusion

In this study, PMR training interventions for 12 weeks significantly improve psychological stress among the students of faculty of sports sciences. The data showed that PMR training interventions program improve psychological stress gradually during the period of treatment which supports the use of this non-drug treatment among psychological stress holders, particularly in younger ages.
