Towards A Successful Peritoneal Dialysis Program

Karkar A

Kanoo Kidney Centre, Dammam Medical Complex, Dammam, Saudi Arabia

Peritoneal dialysis (PD), hemodialysis (HD) and kidney transplantation constitute an integral renal replacement therapy program [1], where end-stage renal disease (ESRD) patients can be shifted to one or more of these treatment modalities according to their assessment and prescription and/or when one of these modalities fails to satisfy its needs [2]. PD has been well established as a first choice renal replacement therapy (RRT) modality with higher survival rate, especially in the first few years of treating ESRD patients [3]. PD, and in particular when there are no contraindications, can be an excellent initial choice and first treatment option (Table 1).

Multiple studies have shown that when compared to HD, PD is associated with equivalent or better survival especially among non-diabetic and younger diabetic patients, where PD has an equal or lower mortality rate during the first 1-2 years of therapy [3-6]. More recent studies have shown that PD and in center HD provide similar short and long term survival [7]. PD has the benefits of preserving residual renal function [8], delaying the need for vascular access and helping patients with multiple vascular access failure, and constitutes a better option for older age groups especially those with cardiovascular disease [8, 10]. PD has been associated with lower risk of infection with hepatitis B and C [11, 12], better outcome after transplantation with lower incidence of acute kidney injury and delayed graft function, lower costs than HD, and in promoting self-care and helping patients who are in need of more freedom [reviewed in 1]. In fact, PD has become an attractive modality of renal replacement therapy following the recent availability of new PD solutions such as icodextrin and amino-acid-based [13, 14] and bio compatible PD fluids [15]. The better understanding of the molecular mechanisms involved in solute and water transport across the peritoneum, the advances in PD technology, and in particular catheter placement [16], better connecting systems with significant reduction in peritonitis rate, and the improved technology of new generation of automated compact easy to use cyclers with many advantages (table 2) have enhanced PD utilization [7]. Studies from the United Kingdom [17] and studies from Netherlands, Belgium and New Haven study [18-20] have documented that if patients are given informed choice of dialysis treatment, 40-60% will choose PD modality. In addition, when comparing patient satisfaction with modality of HD versus PD as in CHOICE study, patients on PD therapy were more satisfied [21]. Furthermore, patients on PD modality from New Haven study were not only more satisfied with their care, but they also felt with less significant impact of PD on their lives [22].

The use of cyclers in North America has increased from 10% in 1990 to 54% in 2000 [23] and in Australia increased from 4% in 1995 to 42% in 2004 [24]. Furthermore, APD has grown steadily in different parts of the world and, for example, it accounts for 35% of the PD patients in Mexico [25]. Globally, it has been estimated that approximately one-third of PD patients are being maintained on APD treatment [26]. In contrast with continuous ambulatory peritoneal dialysis (CAPD), the efficacy of APD, especially in high and high-average peritoneal transport membranes [27], its higher [25] or similar [24, 28] patient and technique survival rates [2], reduced peritonitis rates [2, 25, 29, 30], similar extracellular fluid volume and blood pressure control and sodium removal [31] or enhanced ultrafiltration [32], avoidance of high intraperitoneal pressure and decreased mechanical complications [33], home therapy and improved quality of life with more freedom for patients to fulfill their employment and lifestyle [34], all of which enhanced the popularity of APD modality [35]. These advances have been shown in HD patients transferred to APD [2], and confirmed even for anuric patients as demonstrated in the European Automated Peritoneal Dialysis...
Outcome (EAPOS) Study [36].

However, despite these multiple benefits and advantages there hasn't been much progress [37] but rather a decline in PD utilization in several countries. The penetration rate of PD worldwide is about 11% [35, 38]. PD modality has been declining in most developed countries [39, 40] but increasing in developing countries [35, 41]. In United States, the use of PD has increased appreciably in recent years (7.4% of patients with a known dialysis modality). This change is associated with the new bundled payment system, with its clear incentives for peritoneal dialysis [42]. Likewise, allowing reimbursement of PD, but not HD, has permitted to increase the use of PD over HD in many Asian countries like Hong Kong, Vietnam, Taiwan, Thailand, as well as in New Zealand and Australia over recent years [42, 43]. The major reasons of under utilization of PD modality include (1) lack or inadequate pre-dialysis education [44] and patient's awareness of RRT options [7, 44, 45], and in particular the suitability and advantages of PD modality, (2) insufficient or lack of focus on patients’ training and encouragement and support, especially for anxious and unwell patients who might be nervous about participating in their own treatment [46-48], (3) lack or inadequate training of nursing staff and nephrologists in PD therapy [45, 49], (4) insufficient encouragement and support of medical and nursing staff to guide patients to choose or implement PD modality as a possible first choice therapy [45, 50], (5) lack or insufficient appreciation of the concept of “integrated renal replacement therapy (RRT) program” [1], and (6) inadequate preparation or lack of a proper set up of an independent PD unit [51, 52].

The success and continuity of a PD program relies on different factors including (1) enthusiasm and commitment of the PD team [53, 54], (2) continuous training program for medical and nursing staff, (3) structured educational program for pre-dialysis chronic kidney disease (CKD) patients, (4) application of continuously updated policies and procedures, (5) and continuous evaluation and assessment of the applied program (table 3). Actually, implementation of these major steps should not only lay the foundation for solid PD program, but also should help in providing and maintaining adequate and unified standard technical PD performance [55] and successful continuity of the program (table 4). This approach should be reflected on extended patient’s PD treatment years, as an initial option of RRT, preservation of residual renal function, better preparation of kidney transplantation, delaying or avoidance of HD with vascular access problems, enjoying social life and more freedom together with least technical, infectious and non-infectious complications.

**PD**: Peritoneal Dialysis, **APD**: Automated Peritoneal Dialysis, **CAPD**: Continuous Ambulatory Peritoneal Dialysis, **DM**: Diabetes Mellitus, **IHD**: Ischemic Heart Disease
In conclusion, peritoneal dialysis constitutes an essential part of the integrated renal replacement therapy care for patients with ESRD. Despite the multiple benefits and advantages and improved technology in PD sets, solutions and cyclers, there hasn't been much progress in PD utilization in many countries. The achievement and maintenance of a successful performance of PD unit requires the understanding and implementation of an integrated PD program concept, and the availability of essential needs and requirements. A structured model of PD program should be based on adequate theoretical and practical training of medical and nursing staff, and provides education and practical training of pre-dialysis ESRD patients and those transferred to PD from failed HD treatment. The program should be supported by detailed written and applied PD policies and procedures, including protocols for training and treatment of infections. The establishment of a purpose built, or transformed PD unit, together with continuous evaluation and assessment of performance can ensure the success and continuity. These measures, and the availability of trained and dedicated PD team, and the effectiveness of a training center in unifying the training standards and technique survival in support of PD program, should result in a successful performance and continuity of a PD program.

In conclusion, peritoneal dialysis constitutes an essential part of the integrated renal replacement therapy care for patients with ESRD. Despite the multiple benefits and advantages and improved technology in PD sets, solutions and cyclers, there hasn't been much progress in PD utilization in many countries. The achievement and maintenance of a successful performance of PD unit requires the understanding and implementation of an integrated PD program concept, and the availability of essential needs and requirements. A structured model of PD program should be based on adequate theoretical and practical training of medical and nursing staff, and provides education and practical training of pre-dialysis ESRD patients and those transferred to PD from failed HD treatment. The program should be supported by detailed written and applied PD policies and procedures, including protocols for training and treatment of infections. The establishment of a purpose built, or transformed PD unit, together with continuous evaluation and assessment of performance can ensure the success and continuity. These measures, and the availability of trained and dedicated PD team, and the effectiveness of a training center in unifying the training standards and technique survival in support of PD program, should result in a successful performance and continuity of a PD program.

Table 3: Ten Steps for Implementation of PD Program

1. Adequate training (and re-training) and reorientation of medical staff (doctors and nurses) in principles and practice of peritoneal dialysis.
2. Creation of committed and cooperative PD team (nephrologist / PD nurses / general surgeon or interventional nephrologist / social worker / psychologist / dietician).
3. A basic, but well planned, equipped and organized PD unit (including educational, training and treatment sections).
4. Establishment and regular update of detailed PD policies and procedures.
5. Early approach (in nephrology clinic) of patients with CKD (stage 4).
6. Arrangement for patients to visit the PD unit and meet PD patients.
7. Adequate pre-dialysis education and training of potential PD patients.
8. Back up support: (storage, PD solutions delivery system to patients at home, continuous education, assessment and patient re-training program).
9. Regular and continuous PD education and training of medical staff.
10. Close and continuous monitoring of the PD program: assessment and re-evaluation of clinical outcome, and adjustment of policies and procedures according to results in order to achieve the best out of the PD program.

Table 4: Requirements for Establishing and Succeeding a PD Program

1. Motivation
Well motivated and dedicated team is the cornerstone to a successful PD program. The team should include nephrologists, surgeons, nurses, social workers, and dietitians.

2. Support
Inpatients beds, Back up HD, OPD clinic and training/education rooms.

3. Staffing
Well trained medical /nursing staff to cover patients’ needs on 24h basis.

4. Finances
Financial support is needed for clinical, chemical, and microbiological laboratory, as well as a reliable distribution of PD fluids to patient's homes.

5. Training
A well trained and updated health team is needed to contribute to effective delivery of services. This includes doctors, nurses, and patients.

6. Qualities of a PD nurse
Peritoneal dialysis nurses should have certain qualities to ensure the progress and success PD program. This includes patience, consistency, flexibility, sense of humor, ability to communicate, and good judgment.

7. Protocols
Each unit needs to have protocols for various procedures to ensure safe and consistent care. The required protocols include training program, treatment of infections, laboratory tests and medication, and infection control policies and procedures.

8. Data Recording and Monitoring
Recording and monitoring morbidity and mortality rates as well as incidence of peritonitis should support continuous quality management.
