Protective Effect of Montelukast against Cadmium Induced Pituitary Gland Toxicity

Abd El Azeem EK, Abass MF, Paulis MG, Nisreen Abd-eltawab Abd-Elgaber

Abstract

Cadmium (Cd) is a common environmental hazardous heavy metal. The standard treatment of heavy metal intoxication; chelators may have a minor role in Cd toxicity. Montelukast (ML) is an anti-inflammatory drug that is used mainly for managing asthmatic patients. Recent workers have tested ML for its antioxidant properties in various conditions and obtained encouraging results as regarding this effect. We investigated the protective and antioxidant effect of ML on pituitary gland, a highly sensitive organ to Cd toxicity. Four groups of rats were used and received distilled water, 10mg/kg ML, 3mg/kg Cd, and 10mg ML plus 3mg/kg Cd respectively. Antioxidant, histological, immunohistochemical and hormonal effects of Cd and ML were evaluated. The detrimental effect of Cd on pituitary gland was abolished by ML. The diminished hormonal effect of Cd was restored to normal levels. The increased MDA level and depleted oxidative enzymes on pituitary gland of rat exposed to Cd were restored by ML. Lastly, histological and apoptotic effects of Cd were also, corrected significantly by ML. It is concluded that ML can protect against Cd-induced pituitary gland toxicity.

Keywords: CD; Montelukast; Pituitary; Antioxidant; Apoptosis.

Introduction

Cadmium (Cd) is one of the commonest toxic heavy metal in the surroundings and forms with other heavy metals one of the oldest environmental health problem [1]. It is extensively used in many industries as rechargeable batteries, pigments, radiation screens, etc. In addition, natural health and pharmaceutical products may be sources of Cd exposure. So, we could be exposed to this metal environmentally, occupational and by diet. Cd has serious health hazards that affect most of the tissue types of the human body including reproductive function [2] liver [3] pancreas [4], heart [5] and nervous system [6]. It has been classified as class I human carcinogenic agent [1].

Although, the evidenced high deleterious effect of Cd on the body; there is a shortage in its effective treatment. The standard management of heavy metal intoxication; chelators may have a minor role in Cd toxicity as these therapies have little ability to penetrate cells where most of Cd was stored [1, 7]. With increasing evidence of oxidative stress as a possible mechanism of Cd toxicity [8], variable antioxidants have been tried as possible protective agents in Cd toxicity for example zinc [9] selenium [10], vitamin C and E [11].

Montelukast (ML) is an anti-inflammatory drug with selective reversible cysteinyl leukotriene D4-receptor blocking effect that is used mainly for managing asthmatic patients. Recent workers have tested ML for its antioxidant properties in various conditions and obtained encouraging results as regarding this effect [12]. Most of the studies used ML for acutely intoxicated conditions without looking for subchronic or chronic cases. Also, up to our knowledge, there is no research regarding its protective effect on heavy metal toxicity. So, in this study, we investigated the protective and antioxidant effect of ML on a highly sensitive organ to Cd toxicity; pituitary gland. Hormonal, structural, and antioxidant effects were used to evaluate the toxic effect of Cd and the protective properties of ML.

Materials and Methods

Adult male Sprague rats weighting (220 ± 30gm) were purchased from Faculty of Agriculture, Minia University Egypt. Experimental...
CdCl₂ was obtained from Merck®, Egypt. CdCl₂ anhydrous (99.995%-Cd pure white powder, 25gm package) was prepared by dissolving 50 mg into one liter of distilled water. ML as Singulair® (5mg tablets) produced by Global Napi Pharmaceuticals (GNP) - Egypt. Animals were divided into 4 groups (10 rats each) as follow: the control group received distilled water. Group 2 received ML diluted in distilled water at a dose of 10 mg/kg/day orally [13]. Group 3 received Cd at 3 mg CdCl₂/kg/day (50 mg/l CdCl₂) (this dose produces neuroendocrical disruption) [14]. Group 4 received both ML, plus Cd at a dosage like group 2 and 3. This regimen was followed for 1 month. Rat water consumption does not change throughout the experiment. At the end of the experimental period, animals were killed by decapitation. Trunk blood was collected in tubes containing EDTA and plasma was obtained after centrifugation of the samples at 1,500×g for 15 min at 4°C. Samples were kept frozen at −20°C until hormone measurements. Pituitary gland was removed and frozen for further examination.

For oxidative stress assessment, a part of the pituitary gland was homogenized in cold sodium phosphate buffer (pH 7.4) containing 1mmol/L ethylene diamine tetra acetate acid. The homogenates were then centrifuged at 9000 g for 15 min at 4°C. The supernatants were separated and used for oxidative stress analysis. Four markers were examined to test the antioxidant activities of ML. One of the extensively used tools for evaluating oxidative stress is malondialdehyde (MDA) [15]. Thiobarbituric acid (TBA) method was used to determine MDA level according to Okawa et al., (1979) [16]. Three antioxidant enzymes levels were assayed; namely glutathione reductase (GSH), superoxide dismutase (SOD) and catalase (CAT) according to McGowan (1989) [17], Lu et al., (2013) [18] and Aebi (1984) [19] respectively.

Biopsies from pituitary tissue samples were dehydrated and embedded in paraffin using the routine histological procedures. Serial sections of 6 µm were prepared. The sections were mounted and stained with hematoxylin-eosin. Immunohistochemical Staining

The steps and methods used in immunohistochemical staining were the same followed by Hsu et al., (1981) [20]. In brief; 6µ thickness sections of pituitary tissue and fixed by poly-1-lysine and left for 12 h at 56°C. Sections were deparaffinized by Xylene. 3% H₂O₂ in distilled water was used for inhibiting endogenous oxygenase enzymes. Then sections were washed with phosphate-buffered saline (PBS). Blocking the nonspecific binding of antibodies was done by incubation of the sections in normal goat saline and then rinsed with PBS. Lastly; incubation of the sections with p53 antibodies overnight at 4°C.

A semi-quantitative method for evaluation toxic effect of Cd and protective effect of ML is apoptotic index (AI). AI was determined by counting at least 1000 cells per slide subdivided in 10 fields chosen randomly at x400 magnification. P53 stained nucleus appears dark brown. (Xu et al., 2007) [21].

AI = (number of p53 labeled cells/total number of cells) X 100

Hormonal assay was done using the commercial radioimmunoassay kits. The data were statistically analyzed using SPSS Version 22 software. All data were expressed as means ± standard errors. Data of different groups were compared using ANOVA followed by Mann–Whitney Rank. Differences at p < 0.05 were considered significant.

Results

Table (1) summarizes the effect of Cd on pituitary hormones. Serum prolactin was diminished on rats drinking water containing Cd with high significant change when compared with control group of rats. Other pituitary hormones namely LH, FSH, and GH are also, inversely affected by Cd. It is significantly lower than that of the control. In the administration of ML with Cd, all the examined hormones showed significantly elevation to approximate the normal level, these hormones become insignificantly different from that of control rats.

As regard the oxidative stress effect of Cd, MDA level was significantly higher that of the control in the pituitary tissue. Antioxidant enzymes GRH, CAT, and SOD have significantly depleted in pituitary tissues in rats received Cd. In rats received ML with Cd, there was significantly correction of the oxidative stress produced by Cd in the previous group. This appeared from the corrected MDA and antioxidant enzymes levels (Table 2).

Figure (1) showed the normal histological structure of pituitary gland. Pars distalis forms the main bulk of the anterior pituitary gland. It is formed of acidophils which form the main compo-

Cadmium (Cd) is a ubiquitous heavy metal that is widely distributed in the environment. It is situated in the Periodic Table between zinc (Zn) and mercury (Hg) and has similar chemical characteristics as that of Zn. It usually exists as a divalent cation as between zinc (Zn) and mercury (Hg) and has similar chemical characteristics as that of Zn. It usually exists as a divalent cation as CdCl₂. It is widely used in industry. Smoking represents the most important source of human exposure. CdCl₂ is widely used in industry. Smoking represents the most important source of human exposure [22]. Cd widely affects both haemopoietic, and pancreatic system [3]. In addition, it has carcinogenic properties [23]. In comparison with other toxic agents, Cd occupies the 8th position in the highly toxic 20 chemicals [24].

As regard immunohistochemistry, Figure (4a) shows no immunolabeled cells. Cd received rats, showed an increased number of immunolabeled cells with decreased cell density (Figure 4b). In group received ML and Cd, there were decreasing in the number of immunolabeled cells (Figure 4c). These findings reflected on the calculated AI (Figure 5). AI was significantly higher in Cd group in comparing with control group. In rats received ML plus Cd; AI is significantly decreased to nearly that of the control group.

As regard immunohistochemical examination, there was a significant increase in the expression of p53 protein in rat pituitary gland exposed to Cd in comparing with that of the control. This finding appeared from both microscopic examinations of immunohistologically stained sections and AI calculation. The apoptotic effect of Cd was reported by different authors on pituitary gland [25, 26] and other tissues [27-29]. Cd toxicity produced also, histological changes in rat pituitary tissues. These changes were reported in different studies [30, 31].

As regard immunohistochemical examination, there was a significant increase in the expression of p53 protein in rat pituitary gland exposed to Cd in comparing with that of the control. This finding appeared from both microscopic examinations of immunohistologically stained sections and AI calculation. The apoptotic effect of Cd was reported by different authors on pituitary gland [32, 33] and other tissues [34-36]. Apoptosis or programmed cell death is a gene regulated mechanism that various genes control it. P53 gene is one of them. It presents at a low level in the normal cellular environment but under stressful conditions as excess reactive oxygen species and DNA damage, p53 increases to stop cell growth, repair DNA or if fail, cell death occurs [37]. There are several mechanisms involved in the apoptotic effect of Cd. Oxidative stress and disturbed calcium influx in the cell are the main mentioned causes in the literature [38]. Another mechanism was described by Tokumoto et al., and Lee et al., [39, 40]. They found that Cd suppressed gene expression of the ubiquitin-proteasome system which is responsible for the rapid destruction of this protein system and hence increased

Figure 2. Photomicrographs of the Pituitary gland of CD group showing: a) pars distalis of the adenohypophysis (PD) with congested and dilated sinusoids (arrows), Pars Intermedia (PI), and pars nervosa (PN) of the neurohypophysis. b) PD showing decreased cell amount and congested and dilated sinusoids(s). Acidophils (circle), basophils (blue arrow), and chromophobes (black arrow). H&E aX 10, bX100.

Figure 3. Photomicrographs of the pituitary gland of rats received ML plus Cd showing: a) pars distalis of the adenohypophysis (PD), Pars Intermedia (PI), and pars nervosa (PN) of the neurohypophysis. b) PD with aberrant normal cell amount and sinusoids with no congestion(s). Acidophils (circle), basophils (blue arrow), and chromophobes (black arrow). H&E aX 10, bX100.

Figure 4. Rat pituitary glands labeled for p-53 in a) control and ML groups showed no detectable immunolabeled cells. b) Cd group showed immunolabeled cells (arrows). Notice decreased cellular density. The inset showed immunolabeled cells and p-53-labeled remnants of apoptotic material around and within a sinusoidal lumen (arrows); most probably macrophages phagocytosing remnants of apoptotic cells. c) ML plus Cd showing very few immunolabeled cells (arrow). Immunohistochemistry, counterstained with H x 100.
Montelukast is an oral selective leukotriene receptor antagonist that inhibits cysteine leukotriene. It is widely used as antiasthmatic therapy for chronic asthma and seasonal allergies with high tolerability in both children and adults [41, 42]. It was tested for various pathological conditions as spinal cord injury [43], hippocampal ischemia [44], and hemorrhagic shock [45]. A few years ago, it attracted scientists to be evaluated as a protection for various toxic agents. It gave good results in different acute toxicities in different organs. Examples of these agents are carbon tetra-chloride induced liver injury [46], methotrexate in kidney [47], dioxin and paracetamol in liver [12, 48], gentamicin in kidney [41], indomethacin-induced gastric ulcer [49], paraquat in lung [50], and radioiodine hepatic toxicity [13] but it is not tested against metal-induced toxicity. This study investigated if ML could protect Cd-induced pituitary toxicity. Cd is endocrinal distributors affecting all pituitary hormones; prolactin, GH, LH, and FSH were restored to normal levels by co-administration of Cd and ML. Pituitary gland levels of MDA, GSH, SOD, and CAT were returned to its healthy concentrations by ML. Lastly, ML succeeded in preserving the histological structure of pituitary exposed to Cd and corrected the AI.

The key feature which enabled ML to abolish Cd toxicity may be attributed to its antioxidant properties. MDA concentration in the pituitary gland which produced due to increased lipid peroxidation was restored. The antioxidant enzymes which were depleted by oxidative stress of Cd were restored by ML. The antioxidant effects of ML were reported by other authors [12, 51, 52]. ML has direct free radical scavenger ability in addition to the anti-inflammatory properties which itself diminish the oxidative stress effect on tissues. The anti-inflammatory effect appeared from the disappearance of congested sinusoids in the pituitary gland of rats exposed to Cd and ML. Saad et al., stated that leukotrienes play roles in inflammation and oxidative stress [44].

ML has anti-apoptotic properties. This ability was noticed from the corrected AI in pituitary tissues received Cd plus ML. This effect may be attributed to the antioxidant characteristics of ML. Several studies confirmed the fact of the ability of antioxidants to protect the cells from apoptosis [43, 53]. Another mechanism of anti-apoptotic properties of ML is through inhibition of inflammation [54].

**Conclusion**

This is the first study to reveal the neuroprotective effect of ML on a heavy metal-induced toxicity. ML has both antioxidant and anti-apoptotic protective properties against Cd deleterious effects on the pituitary gland. Further studies are needed to reveal more about the mechanism by which ML protect against Cd-induced toxicity and if it has any beneficial effect on other metals poisoning.
