Abstract

Nevvoid hyperkeratosis of the nipple and areola (NHNA), is a rare benign condition characterized by papular warty excrescences on the nipple, the areola or both. We report a female patient with this rare condition appeared in postpartum and treated successfully by carbon dioxide laser.

Keywords: Nevvoid Hyperkeratosis; Nipple; Areola; Postpartum; Carbon Dioxide Laser.

Introduction

Nevvoid hyperkeratosis of the nipple and areola (NHNA), first described by Tauber [1] in 1923, is a rare benign condition with fewer than 70 cases reported in the literature. Nevvoid hyperkeratosis presents as asymptomatic and hyperpigmented filiform or papular warty excrescences on the nipple, the areola or both. NHNA is commonly bilateral, and appear in women in their second or third decade, at puberty or during pregnancy [2], suggesting the role of hormone in its pathogenesis [1].

We report a female patient with this rare condition appeared in postpartum and treated Successfully by carbon dioxide laser.

Case Report

A 30-year-old woman presented with a 10 year history (just after her first child's birth) of hyperkeratotic and hyperpigmented lesions over her left nipple. She denied associated pain, pruritus, and discharge. The woman had not problems breast-feeding her child. There was no personal or family history of any dermatologic diseases. The evolution was marked for 1 year by the appearance of same lesions on the left areola, concomitant with taking oral contraception.

Physical examination revealed brown irregular verrucous papules and plaques confined on the areola extending to nipple of the left breast (Figure 1). On palpation, the involved skin was not indurated, it was nontender and not adherent to the underlying structures. Breast examination was normal. The right nipple was normal. There was no other cutaneous lesions. There was no discharge from the nipple and no significant lymphadenopathy. Other systems were clinically normal. Dermoscopy’s examination has not shown signs in favor of Bowen’s disease, squamous cell carcinoma or warts (Figure 2).

Histopathologic examination showed hyperkeratosis, papillomatosis, acanthosis, and marked filiform interconnecting elongation of the rete ridges with hyperpigmentation, and keratin-filled spaces and ostia. The dermis revealed the perivascular infiltration of mononuclear inflammatory cells. There was a dense lymphocytic infiltrate in the dermis (Figure 3).

Treatment was performed with carbon dioxide laser. There was a total disappearance of the cutaneous lesions, including those from the nipple and areola (Figure 4). The patient was satisfied with the cosmetic outcome of the therapy. Hormonal contraception has been substituted with another method.

Discussion

NHNA was first described by Tauber in 1923 [1]. Then, Levy-Frankel classified hyperkeratosis of the nipples and areolae into three categories [3]. Type 1 is an extension of epidermal nevus, this usually occurs unilaterally in both sexes. Type 2 is associated with other dermatoses, such as acanthosis nigricans, atopic dermatitis, ichthyosis, Darier disease, or lymphoma. This type may be bilateral. The third type is idiopathic hyperkeratosis of the nipple and areola, this rare condition is also called naevoid hyperkeratosis and it appears predominantly in women in the second or third decade of life, and is usually bilateral [4, 5]. But there are reports of unilateral lesions also [6, 7] like our patient.

The etiology of NHNA is still unknown. A change in estrogen milieu has been proposed as a possible mechanism [8]. Among the cases reported in the literature, one has been reported as having appeared during pregnancy [9]. In another case, nevoid hyperkeratosis appeared in a 60-year-old man with associated glycogenastasia, who developed these lesions after orchidectomy and diethylstilbestrol therapy for cancer of the prostate [10].

In our case, lesions appeared in postpartum and are extended after taking oral contraception, which supports once again hormonal theory in this condition. Typically, NHNA presents as hyperkeratotic, hyperpigmented plaques of the nipple and/or areola [4, 5]. Desquamation [11] or Yellowish discoloration [12, 13] or of the areas may also be present. Occasionally, the lesions appear verrucous [14]. Generally, erythema, induration and discharge do not occur. The lesions may involve the nipple, the areola, or both. Kubota et al., [15] reviewed 45 cases of nevoid hyperkeratosis in which 17% of cases involved the nipple, 25% of cases involved the areola, and the remaining 58% of cases involved both the nipple and the areola.

NHNA is a diagnosis of exclusion [16]. NHNA needs to be differentiated from epidermal naevus, acanthosis nigricans, chronic eczema, atopic eczema, seborrheic keratosi, Darier's disease, Paget's disease, basal cell carcinoma, dermatophytosis, mycosis fungoides and Bowen's disease [14, 17, 18]. These diagnoses were ruled out after dermatoscopic examination in our patient.

These disorders can be distinguished from NHNA by correlating clinical and histological features. There are several histological features which characterize NHNA [6, 17, 18].

The epidermis shows orthokeratotic hyperkeratosis and occasional keratotic plugging. There is marked elongation of the epidermal rete ridges with variable papillomatosis.

The basal layer of the epidermis is hyperpigmented without associated melanocytic proliferation. There may be a mild perivascular lymphocytic infiltrate within the dermis.

The main cause for concern in patients of NHNA is cosmetic appearance of nipple and areola, and rarely may interfere with breast-feeding [7, 11].

Various treatment modalities have been reported including topical corticosteroids, topical calcitriol [19], topical and oral retinoids [20], topical keratolytics, surgical techniques including cryotherapy excision [14, 15, 21, 22], radiofrequency ablation [23], and laser [24]. A case of NHNA was successfully treated with carbon dioxide laser [21] and no recurrence was seen. The current case too was effectively treated with ablative carbon dioxide laser with a good cosmetic outcome. No recurrence has occurred so far, 8 months post-treatment.

Conclusion

NHNA is a rare benign condition. It is a diagnosis of exclusion. Dermoscopy helps to eliminate some differential diagnosis. Biopsy is essential to establish the diagnosis. Various therapies have been used for treatment of HNA with varying extent of efficacy. Our patient will be treated with the ablative carbon dioxide laser, which provides good cosmetic results with a minimum of scarring.
